

Testing document

Functional test

Menu Display and Navigation:

The items are displayed correctly on the screen with the images. Once you click on a product it opens a popup with a description of the product.

The navigation between the categories works correctly and is smooth.

There are no filters for vegan or vegetarian.

Order customization

The user can't customize items to add extra's like (bacon, cheese etc...)

Order placement and payment

The user can add items to the order and it shows up in the basket.

The total price gets calculated. Once the order is placed it also shows the btw calculated.

The app does print and shows an order number.

Special offers and promotions

There are no special offers or promotions.

There are no discount codes.

There are no combo deals.

Order history

The user can view the order history on the end screen.

The order details are also displayed.

There is no re ordering function.

Once you placed an order you go back to the idle screen where you can start a new order.

summary

1. Introduction

The purpose of this functional test is to verify whether the core functionalities of the application work correctly according to the specifications. During the test, several important features of the ordering system were checked, including menu display, navigation, order placement, and order history. The goal of this test is to determine whether users can easily browse the menu, place an order, and view their order details.

2. Test Environment

The functional test was performed on the kiosk ordering application. The test was conducted using a standard device with internet access. Test data included several menu items that were added to the basket to verify ordering and price calculation. No special test accounts were required, as the application allows users to place orders directly from the start screen.

3. Test Scenarios

Several scenarios were tested to verify the main functionalities of the application.

- **Menu display and navigation:**

Menu items were displayed correctly with images. When selecting an item, a popup with the product description appeared. Navigation between different categories worked smoothly.

- **Order customization:**

Users were not able to customize items or add extras such as bacon or cheese.

- **Order placement and payment:**

Users could add items to the basket, and the total price was calculated automatically. After placing the order, the VAT (BTW) was displayed. The application printed the order and generated an order number.

- **Special offers and promotions:**

No special offers, discount codes, or combo deals were available in the application.

- **Order history:**

After completing an order, users could view the order history and order details on the final screen. However, there was no option to reorder previous items. After finishing an order, the system returned to the idle screen to start a new order.

4. Findings

Overall, the main ordering functionality works correctly. Users can browse the menu, add products to the basket, and place an order successfully. However, several features are missing, such as product customization, filters for dietary preferences (e.g., vegan or vegetarian), and promotional options.

5. Improvement Proposals

Based on the test results, several improvements could enhance the application:

- Add customization options for menu items (e.g., extra toppings).
- Implement filters for dietary preferences such as vegan or vegetarian.
- Introduce special offers, discount codes, or combo deals.
- Add a reorder function in the order history to improve user convenience.

Compatibility test:

Introduction:

1. The purpose of the compatibility test is to ensure its compatible with the actual ordering screen and the laptop screen.

That you can use the website on multiple browsers and compatible on certain things

2.

This is on a browser called " Brave & google chrome " it both works fine.

It works on any browser.

Test environment

3. Compatibility Testing

Description of Tests

Compatibility testing was performed to ensure that the kiosk website works correctly across different browsers, devices, and screen resolutions. The tests focused on verifying that the layout, navigation, and interactive

elements behave consistently and remain usable in a kiosk environment, especially with touchscreen interaction and fullscreen display.

Example Test Scenarios

Display of Page Elements in Different Browsers

- Verified that menus, buttons, images, and text render correctly.
- Checked layout consistency across Chrome, Edge, Firefox, and Safari.

Functionality of Forms on Different Devices

- Tested form inputs, dropdowns, and buttons on touchscreen kiosks, tablets, and desktops.
- Verified that form validation and submission work correctly.

Responsiveness on Different Screen Resolutions

- Tested the interface at common resolutions such as 1920×1080, 1366×768, and tablet sizes.
- Ensured content resizes properly and no horizontal scrolling occurs.

4. Findings

Overall, the website functions well across most browsers and devices. Navigation and forms work correctly, and the responsive design adapts to different screen sizes.

Some minor issues were found:

- Slight differences in button styling between browsers.
- Small font rendering differences in Firefox.
- Some clickable elements were slightly small for touch interaction.
- Minor layout overlap at certain screen widths.

5. Improvement Proposals

To improve compatibility across platforms, the following changes are recommended:

- Use a CSS reset or normalization stylesheet to reduce browser differences.
- Increase button and link sizes for better touchscreen usability.
- Adjust responsive breakpoints to prevent layout overlap.
- Apply consistent styling for buttons and form elements across browsers.

These improvements will help ensure a consistent look and smooth functionality across all kiosk platforms.

Performance test

Menu loading time

The menu loads fast but the images have a slight delay with loading. As you can see on the image there are some images with delay in loading.

We could not test different connections.

Order processing time

The order processing time is very fast that works good. When ordering different products its still working good.

Touchscreen responsiveness

The app responds very well to the touches you do.

Under heavy usage it performs good aswell.

Payment processing speed

We could not test this because there was no payment device.

Concurrent user simulation

We could not test multiple users because there was only 1 device.

Summary

1. Introduction

The purpose of the performance test is to measure how well the application performs during normal usage. The test focuses on aspects such as menu loading time, order

processing speed, touchscreen responsiveness, and overall system performance. The goal is to identify possible delays or performance issues.

2. Test Environment

The performance test was performed on a single kiosk device running the ordering application. No external performance testing tools were used. The tests were done manually by interacting with the system, adding products to the basket, and placing orders.

3. Test Scenarios

Several performance aspects of the application were tested.

- **Menu loading time:**
The menu loads quickly, but some product images show a small delay before appearing.
- **Order processing time:**
The order processing time is very fast. Even when ordering multiple products, the system continues to work smoothly.
- **Touchscreen responsiveness:**
The application responds quickly to touch inputs and remains responsive during continuous usage.
- **Payment processing speed:**
This could not be tested because no payment device was connected to the kiosk.
- **Concurrent user simulation:**
Testing multiple users at the same time was not possible because only one device was available.

4. Findings

Overall, the application performs well. The system responds quickly to user actions and processes orders without noticeable delays. The only minor issue observed was a small delay when loading some product images.

5. Improvement Proposals

Based on the test results, the following improvements could be considered:

- Optimize the loading of product images to reduce delays.
- Perform additional tests with multiple devices to simulate concurrent users.
- Test payment processing once a payment terminal is connected.
